Problem Statement

Builders on Portaldot spend their first weeks on infrastructure that has nothing to do with their product. Each team writes its own scraper, stores events in its own schema, decodes contract logs by hand, and quietly accepts gaps when the connection drops. The work is duplicated across every project, the data is inconsistent between them, and the missing ranges are invisible to the people relying on it. That slows every launch and makes the ecosystem look thinner than it is.

01

Every team must build its own scraper

Every Portaldot team has to build and run its own block scraper before it can show a single balance, holder list or contract event.

02

Nodes don’t provide the indexes builders need

Questions like “who holds this token?”, “what does this address own?” and “what did this contract emit?” need a purpose-built index, and a node doesn’t provide one.

PINDEX

Our Solution

01

Metadata-driven indexing

Pindex indexes finalized blocks into a database generated from the chain's own metadata (167 tables on Portaldot, zero per-pallet code) and serves it as a free REST API and a searchable app.

02

Instant decoded events

Register any contract's address and ABI to get one public URL serving its decoded events, and see every coverage gap recorded openly.

Pindex is a shared data layer for Portaldot V3. It reads the runtime metadata, builds a typed table for every event, and follows finalized blocks with a restart-safe cursor. Builders search any native or EVM address, see token holders and NFT owners, and query everything over an open API. A team that deploys a contract pastes its address and ABI and gets a working endpoint for its decoded events, with nothing new to host. Anything the indexer could not read is listed publicly, retried, and marked filled, so builders know exactly what they can trust.

PINDEX

Market Opportunity

Expanding Market Potential

Every dapp on Portaldot needs a data layer, and Pindex is the first one built specifically for its dual contract runtimes, so it can become the default as the ecosystem grows.

PINDEX

Business Model

Stance: Open-core. The code is MIT licensed and anyone can self-host. Hosted Pindex is free and open today. If it earns revenue later, it will do so by being the easiest and most reliable way to run it.

Revenue Streams

Hosted API tiers with higher limits, more contracts, longer retention and webhooks; managed private instances with custom support; ecosystem grants for running the public good; and premium analytics products such as staking and validator data.

Pricing Strategy

Everything is free today: The hosted instance has basic anti-abuse caps, which are not pricing. Paid tiers are not defined and nothing is for sale. If a hosted tier is built, it will be priced for teams that need guaranteed limits and uptime, and the pricing will be decided with real usage data first.

Customer Retention

High switching cost once apps depend on Pindex URLs. Continuous decoded history that teams can’t easily recreate. Public gap tracking builds trust. Webhooks and fast Discord support create daily stickiness. Onboarding takes under five minutes.

Financial Projections

Illustrative model: to be validated

$40 average price per paying customer. Infra costs ~$15/month today. Month-12: Conservative (150 projects, 5% pay) → $320 rev / $170 net; Base (300, 7%) → $840 / $590; Optimistic (600, 10%) → $2,400 / $1,800. Covers hosting but stays small on subscriptions alone. Plan: ecosystem grant first, then grow paid usage.
